

GPT Image 2.5

GPT Image 2.5 - Fast & Reliable GPT Image 2.5 API for Developers

GPT Image 2.5 provides powerful GPT Image 2.5 API access for developers, startups, and businesses to generate high-quality AI images with simple REST endpoints. Build image generation apps, automate creative workflows, and integrate GPT Image 2.5 API into your products instantly.

Production-ready AI image generation and editing

Welcome to the GitHub home of GPT Image 2 API, a browser and API platform for creating polished visual assets from detailed prompts and reference images. It is built for creators, designers, marketers, ecommerce teams, developers, and products that need reliable image generation and targeted editing without maintaining model infrastructure.

The platform focuses on practical creative work: readable text, stable composition, convincing materials, and consistent visual direction. Users can begin in the web interface, iterate on an asset with precise instructions, and then move the same type of workflow into an application through developer-friendly API tasks.

Explore GPT Image 2 (<https://gptimage2api.net/gpt-image-2-api>) · Browse prompts (<https://gptimage2api.net/prompts>) · View the showcase (<https://gptimage2api.net/showcase>) · Read the API docs (<https://gptimage2api.net/docs/api>)

One workflow from brief to production asset

1. Write the brief - Define the subject, environment, composition, lighting, color, materials, typography, and intended channel.
2. Add references - Upload authorized images that communicate identity, product details, layout, style, or brand direction.
3. Generate - Create an initial image from the prompt and reference context.
4. Evaluate - Check subject accuracy, text, hands and objects, materials, spacing, visual hierarchy, and format.
5. Edit precisely - Replace a subject, change a background, correct wording, refine a local region, or adjust the visual style.
6. Create a set - Produce related variations while keeping the key brand or character direction consistent.
7. Export or automate - Download PNG or JPEG output, or submit the validated flow through an API task.

Core capabilities

- Text-to-image generation - create posters, ads, product scenes, illustrations, characters, comics, and design concepts from natural-language prompts.
- Reference-guided creation - use existing images to communicate subject, composition, style, or brand direction.
- Targeted image editing - replace subjects, change backgrounds, update styles, extend a scene, or retouch selected details.
- Readable text rendering - produce visuals that require titles, labels, packaging, signs, or marketing copy.
- Consistent art direction - maintain a coherent look across campaign variations, character sheets, and related outputs.
- Production exports - download finished assets in PNG or JPEG format for downstream design and publishing work.
- Developer API - create keys, submit generation tasks, monitor status, retrieve results, and manage credit-based usage.

Common use cases

GPT Image 2 API is suitable for ecommerce hero images, product mockups, social media graphics, advertising concepts, brand assets, editorial illustrations, presentation visuals, character development, and automated creative features inside SaaS products.

Designed for production details

The platform is especially useful when an image must do more than look interesting:

- Typography and labels - Posters, packaging, signage, diagrams, and social cards often need readable words inside the image.
- Product presentation - Ecommerce work benefits from stable shape, material, color, lighting, and clean backgrounds.
- Campaign consistency - Related ads and posts need a recognizable visual system even when composition changes.
- Targeted revision - A strong image should be repairable without losing every successful decision from the earlier version.
- Reference continuity - Character sheets, branded objects, and recurring scenes benefit from clear source-image guidance.

- Format readiness - Different destinations require deliberate aspect ratio, resolution, file type, and safe text placement.

Generated media still requires human review. Accuracy depends on prompt quality, reference quality, model behavior, selected settings, and the complexity of text or scene details.

For visual and technical teams

- Designers can develop mockups, key art, layout concepts, and rapid visual directions.
- Marketing teams can produce campaign variants, social graphics, posters, and ad concepts.
- Ecommerce teams can create product scenes, hero imagery, comparison graphics, and merchandising assets.
- Creators and storytellers can explore characters, comics, scenes, and consistent visual series.
- Developers can add managed image generation and editing to SaaS products or internal tools.

A practical API workflow

1. Create an API key and keep it in a secure server-side environment;
2. Select a supported image model and prepare the prompt, references, and output options;
3. Submit a generation or editing task with authenticated API access;
4. Retain the task ID and poll until the task succeeds or fails;
5. Validate and store the returned asset according to the application's privacy and retention rules;
6. Track history and credit usage, and handle rate limits, retries, timeouts, and provider failures.

Do not expose secret keys in browser code or public repositories. Applications should also validate upload rights, moderate inputs and outputs, and communicate generation status clearly to users.

Product principles

- Production quality over novelty alone - Composition, text, material, and export usefulness matter.
- Editing is part of generation - A strong workflow supports correction and refinement after the first result.
- References are creative controls - Source images should guide identity and design without replacing user judgment.
- Browser and API parity - Interactive learning should translate into repeatable developer tasks.

- Human review remains essential - Every asset should be checked for accuracy, rights, safety, and brand fit.

From concept to production

1. Describe the subject, composition, lighting, text, format, and intended use.
2. Add reference images when visual continuity or targeted editing matters.
3. Generate and refine the output until it meets the production goal.
4. Export the asset, or use an API key to run the workflow programmatically.
